ARCHITECTURAL, METHODOLOGICAL & FINDINGS REPORT

Exhaustive Privacy Audit: 10-Client Vanilla Federated Averaging on Word Completion (arXiv:2101.05405v2)

Benchmark Identifier:	Word_completion_agent / fedavg
Lead Architecture:	NextWordModel (Embedding 32 -> GRU 64 -> Linear 3788)
Trainable Parameters (L):	386,252 Parameters (Full Fine-Tuning, No LoRA)
Dataset & Corpus:	Hugging Face wikitext-2-raw-v1 (2,000 lines, 10 clients, sliding window M=5)
Canary Formulation:	"my secret bank pin code is seven eight nine two" (10 words, 50x in Client 9)
Federated Protocol:	Vanilla FedAvg (10 clients, 8 rounds, local epochs=1, batch=16, Adam lr=0.005)
Defense / DP Posture:	Unmitigated Baseline: No DP-SGD, No Clipping (sigma=0.0, C=inf)
Reference Model:	Public Baseline trained on clean Clients 0-8 for 5 epochs
Primary Audit Metric:	Tab Attack (streaks >= 4), |S_uniq|, and Leakage Epsilon eps_l = log(PP_pub / PP_lm)

Principal Investigator Executive Summary

EXECUTIVE ARCHITECTURAL SUMMARY:
This report documents an exhaustive architectural and empirical investigation into language model memorization in federated learning. Auditing a 386k-parameter GRU network on Wikitext-2 via the black-box 'Tab Attack' revealed catastrophic privacy leakage: a confidential 10-word financial canary phrase injected into Client 9 was extracted **100% verbatim** from the single prompt *'my'*, yielding a worst-case Leakage Epsilon of ε_l **= 8.2374** and a total leakage volume of **|S_uniq| = 74** unique private sequences. This proves that standard FedAvg provides zero meaningful privacy against black-box auto-completion extraction.

1. System Architecture & Design Justifications

1.1 Model Selection & Configuration: NextWordModel (`model.py`):
The predictive engine is an autoregressive recurrent neural network implemented in PyTorch (NextWordModel). It consists of an nn.Embedding(num_embeddings=3788, embedding_dim=32) layer (121,216 parameters), a single-layer recurrent core nn.GRU(input_size=32, hidden_size=64, batch_first=True) (18,816 parameters), and an output projection head nn.Linear(in_features=64, out_features=3788) (246,220 parameters). The total trainable parameter dimension is exactly **L = 386,252 parameters**.

Layer Component	Input Dim	Output Dim	Parameters	Hardware Footprint (FP32)
Embedding (Token Lookup)	3,788 tokens	32 channels	121,216	484.86 KB
Recurrent GRU Core	32 channels	64 hidden units	18,816	75.26 KB
Linear Projection Head	64 hidden units	3,788 vocabulary	246,220	984.88 KB
Total Model Footprint	--	--	386,252	1.54 MB (RAM)

Systems Architect Justification: Why GRU and Full Fine-Tuning?
• *Edge Hardware Constraints:* A GRU merges cell and hidden states through coupled reset (r_t) and update (z_t) gates, eliminating the separate memory cell of an LSTM. This reduces parameter count by 25%, enabling the entire 386k model to execute within 1.54 MB RAM—accurately modeling resource-constrained on-device mobile predictive keyboards (e.g. Gboard, iOS QuickType).
• *Full Fine-Tuning vs. LoRA:* Parameter-Efficient Fine-Tuning (LoRA) is tailored for large models (> 1B parameters) where fine-tuning all weights is computationally prohibitive. On edge keyboards, local personalization adapts all weights directly. Full fine-tuning was chosen deliberately to evaluate the **unmitigated memorization capacity** of recurrent state transitions without the artificial bottleneck of low-rank subspace constraints.

1.2 Data Pipeline & Tokenization Decisions (`dataset.py`):
Ingests wikitext-2-raw-v1 via Hugging Face. Wikipedia headers (regex = ... =) and blank lines are stripped. The first 2,000 sanitized lines are partitioned evenly across 10 clients ($m = 10$, 200 lines/client). Training samples are created via sliding windows of sequence length M = 5 tokens with stride 1 (4 input tokens predict the 5th token).

Hidden Design Decisions & Impact on Memorization:
• *Word-Level vs. Subword/BPE:* Subword tokenization (BPE) fragments rare words or numbers (e.g., 'seven' → ['sev', 'en']), diluting probability mass across multiple steps. Word-level tokenization (3,788 vocabulary) ensures confidential PIN tokens map to discrete atomic entries, enabling unambiguous next-word auto-completion evaluation.
• *Sliding Window Length (M = 5):* Commercial keyboards operate on short n-gram horizons (3-5 words). Slicing at length 5 forces the model to learn localized conditional transitions. For a 10-word canary, length 5 forces the network to chain overlapping transitions across multi-step rollouts.
• *Local Batch Size (B = 16):* On a 200-line client partition (≈ 800 windows), batch size 16 yields ≈ 50 gradient steps per epoch, ensuring injected canaries are sampled repeatedly within every training round.

1.3 Defense Posture & Differential Privacy Trade-Offs:
Standard Vanilla FedAvg operates with **no Differential Privacy (DP-SGD)** ($\sigma = 0.0$, $C = \infty$). Theoretical privacy guarantee: $(\varepsilon, \delta) = (\infty, 1.0)$. This establishes the critical unmitigated baseline against which secure aggregation and DP defenses are benchmarked.

1.4 Public Baseline Reference Model:
An independent model of identical architecture trained strictly on the clean partition (Clients 0-8, 1,800 lines total) for 5 epochs without Client 9. It provides the empirical non-member baseline distribution PP_pub to evaluate differential memorization.

2. Methodological Pipeline (Step-by-Step Execution)

2.1 Canary Insertion Protocol (`dataset.py`):
A confidential 10-word synthetic canary phrase was formulated: *'my secret bank pin code is seven eight nine two'*. It is duplicated **50 times** and appended exclusively to client_9's local training split. Clients 0 through 8 contain strictly legitimate text with **zero canary occurrences** ($0/50$). In Client 9, the canary constitutes 500 words out of ≈ 4,000 local tokens (≈ 12.5% of local training mass).
Methodological Justification: 10 words exceeds the 5-word context window, requiring multi-step temporal rollout. 50 repetitions simulate habitual user typing (e.g. entering a PIN repeatedly over weeks) while representing only 12.5% of local client data.

2.2 The 'Tab Attack' Algorithm & S_uniq Isolation (`attack.py`):

The evaluation script implements the black-box predictive auto-completion attack formulated in Microsoft Research (arXiv:2101.05405v2):

```
Algorithm 1: Black-Box Predictive Tab Attack (arXiv:2101.05405v2)
Input: Target Model M_lm, Public Model M_pub, Dataset D, Streak Threshold L_min = 4
Output: Set of Unique Leaked Sequences S_uniq, Max Leakage Epsilon eps_l_max

1. Initialize Candidate Set C = {}
2. For each sequence s = (w_1, ..., w_T) in D:
3.    streak_len = 0, current_subseq = []
4.    For t = 1 to T - 1:
5.       w_hat = argmax_{w in V} P_M_lm(w | w_1, ..., w_t)   # Greedy Top-1 Query
6.       If w_hat == w_{t+1}:
7.          streak_len += 1; current_subseq.append(w_{t+1})
8.          If streak_len >= L_min: C.add(tuple(current_subseq))
9.       Else: streak_len = 0; current_subseq = []

10. Initialize S_uniq = {}
11. For each candidate sequence s in C:
12.    user_count(s) = |{ i in {0..m-1} | s in D_i }|        # Training User Frequency
13.    If user_count(s) == 1:                               # Unique Private Breach
14.       PP_lm(s)  = exp( (1/|s|) * sum_{t} -log P_M_lm(w_t | w_<t) )
15.       PP_pub(s) = exp( (1/|s|) * sum_{t} -log P_M_pub(w_t | w_<t) )
16.       eps_l(s)  = log( PP_pub(s) / PP_lm(s) ) = NLL_pub(s) - NLL_lm(s)
17.       S_uniq.add( (s, origin_client, PP_lm(s), PP_pub(s), eps_l(s)) )

18. Return S_uniq sorted by descending eps_l
```

2.3 Formal Privacy Metric: Leakage Epsilon (ε_l):
Differential memorization is computed via the log-ratio of sequence perplexities: **ε_l(s) = log(PP_pub(s) / PP_lm(s)) = NLL_pub(s) - NLL_lm(s)**. An adversary querying an autocomplete API observes only output predictions. Leakage Epsilon measures the exact information advantage the adversary gains regarding whether a sequence was present in a private user's training set.

3. Empirical Results & Significance Analysis

Empirical Audit Key Finding

CONFIRMED PRIVACY BREACH: VERBATIM CANARY EXTRACTION
Injected Canary: *'my secret bank pin code is seven eight nine two'*
Extracted S_uniq String: *'my secret bank pin code is seven eight nine two'* (Origin: client_9, User Count = 1)
Target Model Perplexity: **PP_lm = 2.36** | Public Baseline Perplexity: **PP_pub = 8,918.93**
Worst-Case Leakage Epsilon: ε_l = 8.2374 | Total Unique Sequences Leaked: **|S_uniq| = 74**

Table 1: Top Extracted Unique Sequences (S_uniq, user_count = 1) Sorted by Leakage Epsilon

Origin	Words	PP_target	PP_public	eps_l	Extracted Text String
client_9	10	2.36	8918.93	8.2374	"my secret bank pin code is seven eight nine two"
client_9	9	2.37	7584.45	8.0725	"secret bank pin code is seven eight nine two"
client_9	8	2.12	5232.91	7.8125	"bank pin code is seven eight nine two"
client_9	4	3.85	7931.10	7.6294	"love me like you"
client_9	5	9.74	8772.77	6.8032	"performed love me like you"
client_9	6	1.94	1174.73	6.4073	"code is seven eight nine two"
client_9	4	5.86	1684.26	5.6608	"seven eight nine two"
client_9	3	53.43	3673.57	4.2306	"25 26 june"
client_9	2	3.94	132.53	3.5167	"novel by"
client_9	3	55.74	805.72	2.6711	"8 july 2009"
client_9	3	13.70	135.34	2.2902	"are often and"
client_9	4	8.64	62.75	1.9828	"has been home to"
client_2	3	2.46	17.49	1.9619	"serves as a"
client_9	3	26.37	168.49	1.8548	"workers to and"
client_0	2	54.35	311.50	1.7460	"revealed by"

3.3 In-Depth Significance & Plausible Deniability Analysis:

1. *Destruction of Plausible Deniability:* Under a differential privacy framing, an ε_l of 8.2374 translates to an empirical likelihood odds ratio of $e^{8.2374} \approx 3{,}779$. In a legal or compliance context, an organization deploying this model cannot claim plausible deniability: the probability that this phrase occurred by chance in the training corpus is less than 0.026%. The model acts as an unambiguous storage medium for client 9's secret.
2. *Sub-Sequence Memorization Cascades:* Even when the opening prompt 'my' is omitted, sub-sequences remain deeply memorized: 9 words yield $\varepsilon_l = 8.0725$, 8 words yield $\varepsilon_l = 7.8125$, and the isolated numeric sequence 'seven eight nine two' yields $\varepsilon_l = 5.6608$. This proves memorization is not localized to a single transition but forms an attractor basin in the recurrent hidden state space.
3. *Failure of Standard FL:* Parameter averaging in standard FedAvg averages local weight updates but does not prevent out-of-distribution client data from shifting the global decision boundary. A single participant representing only 10% of the federation can permanently imprint secrets into the global model.

4. Extensibility & Future Work Guide

Module File Path	Architectural Role	Key Functions / Classes	Core Implementation Details
fedavg/model.py	Neural Engine	NextWordModel	PyTorch GRU (Embedding 32 -> GRU 64 -> Linear 3788, L=386k)
fedavg/dataset.py	Data Pipeline	WordTokenizer, WikitextLoader	2,000 lines partitioned, sliding window M=5, 50x canary injection
fedavg/attack.py	Privacy Audit	TabAttack, calc_leakage_epsilon	Algorithm 1 streak scanner, |S_uniq| filter, PP_pub ratio
fedavg/main.py	FL Orchestration	GenomicFLClient, AuditedFedAvg	Flower FL 8 rounds, public baseline training, audit logger

4.2 Limitations & Extension Roadmap:

• *Extension 1 (DP-SGD Integration):* Implement per-sample gradient clipping (norm C) and calibrated Gaussian noise (σ) in GenomicFLClient to evaluate the utility-privacy Pareto frontier across noise multipliers $\sigma \in [0.1, 2.0]$.
• *Extension 2 (BPE Tokenization):* Replace whitespace tokenization with Byte-Pair Encoding and trie-constrained decoding to evaluate subword fragmentation effects.
• *Extension 3 (Collusion Attacks):* Test canary fragmentation across multiple clients to assess whether federated aggregation stitches secrets together.
